Abstract

Aim: To determine the prevalence and pattern of retinal vascular disorders in pregnant women.

Materials and Methods: This hospital based, prospective observational study was conducted over a period of two years. Patients were selected from outpatient department and antenatal ward of Department of Obstetrics and Gynecology and outpatient department of Ophthalmology, SS Hospital, IMS, BHU, Varanasi. In all cases detailed obstetric history including age, gravida, gestational age, general and antenatal examination and relevant pathological investigations like blood sugar, blood urea, serum creatinine and urinary protein were carried out. After taking ocular history, detailed ocular examination including visual acuity and fundus examination under mydriasis with 1% tropicamide eye drop was carried out. All the findings were recorded on a data sheet and were analyzed using SPSS programme. The Chi-Square test was used to evaluate the association between the various antenatal factors and retinal vascular changes.

Results: Of 210 patients 38.09% patients were primigravida and 28.57% were second gravida. 28.57% had pregnancy induced hypertension (PIH), 13.33 % had gestational diabetes mellitus, 12.38% had preexisting diabetes mellitus. Fundus abnormalities were observed in 110 (52.38%) cases among them commonest retinal pathology was hypertensive retinopathy 38 (34.55%) followed by diabetic retinopathy (32.73%), retinal vein occlusion (16.36%) and central serous chorioretinopathy (7.27%). Out of 60 cases of PIH 38 (63.33%) had retinal abnormalities. Retinal vascular disorders were seen in > 80% cases of severe pre-eclampsia and about 90% cases of eclampsia. Majority (68.42%) of PIH patient had grade I hypertensive retinopathy. The commonest retinal change was arterial attenuation (28.57%) followed by dot and blot hemorrhage (21.90%), A-V crossing changes (20.48%), hard exudates (19.05%), flame shaped hemorrhage (42.56%) and macular edema (18.10%). However in 5.71% cases papilledema and in 5.24% cases ischemic optic neuropathy was observed

Conclusion: The most common vision threatening retinal vascular disorders in pregnancy was hypertensive retinopathy (34.55%) followed by non proliferative diabetic retinopathy (32.73%), pregnancy associated venous occlusive disorders of retina (16.36 %) and central serous chorioretinopathy (7.27%). Other retinal abnormalities seen in pregnancy included optic neuritis, papilledema and macular edema. Pregnancy may be one of the risk factors for retinal vasculopathy and temporary visual impairment. Thus, ocular fundus examination may be a valuable and necessary routine investigative procedure in pregnancy.

Keywords: Diabetic retinopathy, Eclampsia, Hypertensive retinopathy, Ophthalmoscopy, Pre-eclampsia, Pregnancy induced retinal disorders.

Introduction

Pregnancy can cause changes in eyes of healthy women as well as in those having pre-existing systemic diseases like diabetes mellitus and hypertension. Ocular manifestations during pregnancy can be caused by physiological changes, pregnancy specific eye disorders and worsening of pre-existing retinal disorders. Retinal vascular abnormality during pregnancy mainly occurs as a result of haematologic, hormonal, metabolic and cardiovascular changes.¹

The most common retinal vascular disorder altered by pregnancy is diabetic retinopathy (DR). Progression of diabetic retinopathy during pregnancy may be due to risk factors such as hypertension, obesity and poor glycemic control. Other retinal and chorioretinal disorders associated with pregnancy include central serous chorioretinopathy and occlusive vasculopathy such as retinal artery occlusion and retinal vein occlusion, most common sight threatening conditions.²⁻⁵ During pregnancy thromboembolic events take place due to hypercoagulable states with an increase in thrombin levels, decrease in the levels of endogenous

anticoagulants and venous stasis due to effect of progesterone on blood vessel walls.^{2,6} The increased risk of thromboembolic disorders during pregnancy may lead to occlusive vasculopathy. Pregnancy Induced Hypertension (PIH) is a specific cause of retinopathy which affects 5-10% of all pregnancy worldwide.⁷ Retinal involvement is common in PIH occurring in about 30-100% of patients.⁸

PIH is a hypertensive disorder of pregnancy that occurs after 20 weeks of gestation in the absence of other causes of raised blood pressure (> 140/90 mm of Hg) associated with anasarca and or proteinuria (>300mg/24 hrs). PIH with significant proteinuria is called Pre-eclampsia and when associated with convulsions or coma is called Eclampsia.

It has been reported that vision threatening retinal changes in patients with preeclampsia and eclampsia are acute ischemic optic neuropathy, central serous retinopathy, maculopathy, central retinal vein occlusion, retinal detachment and choroidal ischemia.⁹⁻¹³ In spite of wide spectrum of retinal lesions occurring in pregnancy very little study have been reported from

North India. Therefore this study was done to determine the prevalence and pattern of retinal vascular disorders during pregnancy.

Materials and Methods

This hospital based, prospective, observational study was conducted jointly by Department of Ophthalmology and Obstetrics and Gynecology, S.S. Hospital, Institute of Medical Sciences, Banaras Hindu University, Varanasi between December 2016 and January 2018. Cases were randomly selected from antenatal clinic and wards of Department of Obstetrics and Gynecology and Ophthalmology OPD. All pregnant women willing to participate were included in this study. Patients who had history of ocular trauma, surgery, laser treatment and hazy ocular media were excluded from the study. The study was approved by Institute Ethical Committee.

After obtaining an informed consent, patients were thoroughly evaluated by an Obstetrician. Detailed antenatal history, general, physical and systemic examinations and relevant investigations like routine blood count, HIV, HBsAg, blood sugar, renal function test, TORCH profile and USG Abdomen etc. were carried out.

Detailed ocular history and examination like visual acuity, slit lamp biomicroscopy, Goldmann applanation tonometry and fundus examination under 1% tropicamide eye drop with direct ophthalmoscope in dark room were done in all patients. Fundus photographs were taken for documentation. Fundus findings such as changes in size, shape and color of disc, disc margin, cup:disc ratio, changes in caliber of retinal vessels, arterio-venous ratio, vascular blood column, AV crossings, changes in macular area and presence of hemorrhage, exudates etc. were recorded. Keith – Wagener classification was used for grading the hypertensive retinopathy as below:

Grade 1: Mild generalized arterial attenuation, particularly of small branches;

Grade 2: More severe Grade 1 + focal arteriolar attenuation;

Grade 3: Grade 2 + hemorrhages, hard exudates, cotton wool spots;

Grade 4: Grade 3 + optic disc swelling.

Data collected were analyzed using SPSS software version 18. Chi-Square test was applied. P-value <0.05 was considered statistically significant.

Results

Maximum number of patients (57.14%) belonged to age group 21-25 years. (Table 1)

Table 1: Age wise distribution of study subjects

Age in years	Number	Percentage
Upto 20	38	18.10
21-25	120	57.14
26-30	22	10.48
31-35	20	9.52
>35	10	4.76
Total	210	

Out of total 210 patients examined, 52.38% had retinal disorder. The mean age was 24.58±2.46 year (range 18-43 years). The gestational period ranged between 20-37 weeks. 80 women (38.10%) were primigravida, 60 (28.57%) were second gravida and 37 (17.62%) were third gravida. In primigravida and second gravida about 53% had retinal disorders while 80% of fifth gravida and 56% of fourth gravida had retinal disorder.

Table 3 shows that pregnancy induced hypertension (PIH) was found in 60 (28.57%) patients, gestational diabetes in 28 (13.33%), pre-existing diabetes in 26 (12.35%) and pre-existing hypertension in 16 (7.82%) while rest were normal.

Out of 210 (52.35%) patients 110(52.38%) had retinal disorders, 34.55% had hypertensive retinopathy, 32.73% had diabetic retinopathy, 16.36% had retinal vein occlusion, 7.27% had central serous chorioretinopathy and 5.45% had ischemic optic neuropathy.(Table 4, Fig. 1-8)

Table 2: Distribution according to number of gravida and retinal abnormality

Gravida	Number	Retinal abnormality
Primi	80	43 (53.75%)
Second	60	32 (53.33%)
Third	37	16 (43.24%)
Fourth	18	10 (55.56%)
Fifth	10	8 (80.00%)
Onwards	5	3 (60.00%)

Table 3: Distribution according to antenatal conditions

Status	Number	Percentage
Normal	80	38.09
Pre-existing DM	26	12.38
Pre-existing HTN	16	7.61
PIH	60	28.57
Gestational DM	28	13.33
Total	210	

Table 4: Distribution according to retinal pathology (N=110)

Retinal Pathology	Number	Percentage
Hypertensive retinopathy	38	34.55
Diabetic retinopathy	36	32.73
Retinal vein occlusion	18	16.36
Central serous retinopathy	8	7.27
Optic neuropathy	6	5.45
Others	4	3.64

Fig. 1: Fundus photograph of left eye showing features of Grade 4 Hypertensive Retinopathy

Fig. 2: Fundus photograph of Right Eye showing features of Mild Non-Proliferative Diabetic Retinopathy (NPDR)

Fig. 3: Fundus photograph of Right Eye showing features of Moderate Non-Proliferative Diabetic Retinopathy (NPDR) with Cystoids Macular Edema (CME)

Fig. 4: Fundus photograph of Left Eye showing features of very Severe Non-Proliferative Diabetic Retinopathy

Retinopathy (NPDR) with Cystoids Macular Edema (CME)

Fig. 5: Fundus photograph of Right Eye showing features of Central Retinal Vein Occlusion (CRVO)

Fig. 6: Fundus photograph of Right Eye showing features of Inferotemporal Branch Retinal Vein Occlusion (BRVO)

Fig. 7: Fundus photograph of Right Eye showing features of Superotemporal Branch Retinal Vein Occlusion (BRVO)

No retinal changes were seen in 47.62% of the patients. The commonest retinal change was arterial attenuation (28.57%) followed by dot and blot haemorrhage (21.90%), A-V crossing changes (20.48%), hard exudates (19.05%), flame shaped haemorrhage (42.56%) and macular edema (18.10%). However in 5.71% cases papilledema and in 5.24% cases ischemic optic neuropathy was observed. (Table 5).

Table 5: Distribution according to fundus findings (N=210)

Fundus Findings	Number	Percentage
Normal	100	47.62
Arterial attenuation	60	28.57
AV crossing changes	43	20.48
Flame shaped haemorrhage	90	42.56
Dot and blot haemorrhage	46	21.90
Pre-retinal haemorrhage	06	2.86
Hard exudates	40	19.05
Cotton wool spots	32	15.24
Papilledema	12	5.71
Retinal edema	22	10.48
Optic neuropathy	11	5.24
Macular edema	38	18.10
Retinal detachment	4	1.90

In our study, out of 60 cases of PIH 38(63.33%) had retinal abnormality. Retinal vascular disorders were seen in more than 80% cases of severe pre-eclampsia and about 90% cases of eclampsia. (Table 6)

Table 6: Distribution according to number of PIH cases and retinal abnormality

Type of PIH	Number of cases	No. of cases with retinal disorders
Gestational hypertension	2	0
Mild pre-eclampsia	24	9 (37.50%)
Severe pre-eclampsia	16	13 (81.25%)
eclampsia	18	16 (88.89%)
others	0	0
total	60	38 (63.33%)

Out of 38 cases of hypertensive retinopathy, 26 (68.42%) had grade I hypertensive retinopathy, 8 (21.05%) had grade II hypertensive retinopathy while 4 (10.53%) had grade III hypertensive retinopathy. (Table 7)

Table 7: Grade of hypertensive retinopathy in our patients

Grade	Number	Percentage
I	26	68.42
II	8	21.05
III	4	10.53
IV	0	0
Total	38	100.0

Discussion

The vision threatening conditions in pregnancy are not uncommon. Though, hypertensive disorders in pregnancy is a major health issue in developing countries responsible for both maternal and fetal mortality but eyes are rarely examined unless serious complications like severe pre-eclampsia or eclampsia occurs.

In our study, the incidence of PIH as well as retinal changes is more common in age group of 21-25 years. Similar findings were reported in study of Bakhada RN¹⁴ Neutra RR reported that women under 20 years were six to seven times more susceptible than those in age 25-29 years.¹⁵

In the present study, overall positive fundus findings were seen in 52.35% cases. Reddy¹⁶ also reported overall positive fundus finding in 59% cases. Tadin et al¹⁷ from Croatia reported 45% of retinal

changes in their study of 40 cases of PIH, but Karki et al¹⁸ from Nepal reported 13.7% of positive fundus changes in their study of 153 subjects.

The incidence of PIH is more common in primigravida or second gravida because young arterioles are more sensitive to high blood pressure.¹⁴

In this study hypertensive retinopathy changes were seen in 34.55% cases. Most of the hypertensive retinal changes were grade I or grade II retinopathy changes. Ranjan R et al¹⁹ reported hypertensive retinopathy changes in 40% of patients with PIH. Majority of them were grade I retinopathy. The progression of retinal vascular changes and retinal edema is suggestive of severity of PIH.^{14,20,21}

In our study 36(17.14%) cases had retinal findings suggestive of diabetic retinopathy and 16.36% had retinal vein occlusion. 13.33% patients had gestational diabetes mellitus and 12.35% had pre-existing diabetes mellitus. The gestational diabetes and pre-existing diabetes mellitus may deteriorate during pregnancy. DM in pregnancy may lead to development of retinal vein occlusion (RVO).^{1,22}

The commonest retinal changes noted were arterial attenuation (28.57%) followed by dot and blot haemorrhage (21.90%), AV crossing changes (20.45%) and macular edema (18.10%). However, 1.90% cases had retinal detachment. Fry et al²³ reported retinal

detachment in 1.20% cases. Bosco et al²⁴ reported bilateral retinal detachment in 7 cases.

The presence of retinal haemorrhage, macular edema, papilledema and retinal detachment are the indications of termination of pregnancy to save mother and child.²⁵

Conclusion

The most common vision threatening retinal vascular disorders in pregnancy was hypertensive retinopathy (34.55%) followed by non proliferative diabetic retinopathy (32.73%), pregnancy associated venous occlusive disorders of retina (16.36 %) and central serous chorioretinopathy (7.27%). Other retinal abnormalities seen in pregnancy included optic neuritis, papilledema and macular edema. Pregnancy may be one of the risk factors for retinal vasculopathy and temporary visual impairment. Thus, ocular fundus examination may be a valuable and necessary routine investigative procedure in pregnancy.
